Abstract

Rationale: Tumor cells are ideal candidates for developing cancer vaccines due to their antigenic profiles, yet existing whole-cell vaccines lack efficacy. This study aimed to develop a novel whole-cell vaccine platform that combines immunogenicity, structural integrity, and tumor-targeting capabilities.

Methods: We created "Magnetic Sculpture-like (MASK) Cells" by treating tumor cells with high-concentration $FeCl_3$, inducing rapid morphological fixation without traditional chemical crosslinking. MASK cells were characterized for proliferative capacity, biomolecule retention, and magnetic properties. Vaccine efficacy was tested *in vitro*, in melanoma-bearing mouse models, and through spatial transcriptomic profiling of tumor microenvironments. Combination therapy with anti-PD-1 was further evaluated.

Results: MASK cells lose proliferative ability but retain biomolecules and architecture. MASK cells promote dendritic cell maturation and T cell responses against tumors. Vaccines combining MASK cells and adjuvant potently suppress melanoma growth. Uniquely, $FeCl_3$ sculpting imparts magnetism to cells, enabling directional navigation to tumors using magnetic fields and enhanced in situ immune activation. Spatial transcriptomics reveals DC and T cell activation and tumor cytotoxicity after MASK vaccination. Combined with anti-PD-1, MASK cell vaccines strongly inhibit growth and improve survival.

Conclusion: MASK cells represent a promising new approach for targeted, patient-specific anti-tumor therapeutics.

Keywords: Immunotherapy; Whole-cell vaccines; Magnetic Sculpture-like cell.

Introduction

Cancer vaccines represent a promising immunotherapy strategy that harnesses the patient's adaptive immune system to combat malignant tumors. These vaccines work by stimulating immune responses against specific tumor antigens, with the key requirement being the efficient delivery of high-quality antigens to dendritic cells (DCs) for optimal activation [1-4]. However, current limitations in sequencing and bioinformatics technology restrict our ability to identify and quantify tumor-specific antigens in individual samples [5, 6], hampering the development of timely personalized treatments.

Whole tumor cell vaccines have emerged as a compelling solution to this challenge. Since autologous tumor cells naturally carry diverse tumor-specific antigens, they serve as an ideal antigen source for cancer vaccine preparation [7-9]. These techniques have demonstrated success in generating robust antitumor immune responses across various cancer types [9-15]. However, existing methods face significant limitations, particularly in terms of stimulating tumor immunogenicity [16] and achieving precise targeting to avoid damage to normal cells [17]. These challenges have restricted their clinical application [18, 19], highlighting the need for innovative therapeutic strategies.

Immune checkpoint blockade (ICB) drugs represent another significant advancement in cancer immunotherapy, achieving remarkable success in clinical practice. While ICB treatments have revolutionized cancer care and improved remission rates [1], their effectiveness varies considerably across cancer types, and many patients show resistance to these treatments [20, 21]. This variable response has led to the exploration of combination therapies. The integration of therapeutic whole tumor cell vaccines with ICB drugs presents a particularly promising approach, leveraging both tumor antigen specificity and immune checkpoint inhibition to potentially enhance overall response rates and achieve more durable therapeutic outcomes [1, 22].

In our investigation of novel vaccine approaches, we discovered an unexpected phenomenon when treating tumor cells with 100 mM $FeCl_3$ solution. Under phase contrast microscopy, we observed distinct morphological changes, characterized by enhanced contrast between cell and nuclear membranes. The cells underwent a transformation within approximately 30 s, assuming a distinctive sculpture-like appearance. While this process shares similarities with cell fixation, it

differs significantly from conventional paraformaldehyde (PFA) fixation, leading us to designate these transformed cells as Sculpture-Like Cells (SLCs). Further investigation revealed that these cells possess magnetic properties, enabling their concentration within solid tumors under magnetic field guidance. This capability to effectively activate localized immune responses in tumor regions led to their alternative designation as Magnetic Sculpture-like (MASK) cells. These MASK cells present a potential solution to the limited response rates observed with existing tumor vaccines and show promise as a novel targeted, personalized therapeutic vaccine. Moreover, their potential synergy with ICB drugs suggests opportunities for enhanced antitumor effects through combination therapy.

Methods

Animals

Four to six-week-old male and female C57BL/6, BALB/c mice were purchased from Beijing Vital River Laboratory Animal Technology Co., Ltd. and acclimatized for one week in the specific pathogen-free facilities before performing experiments. They were kept in individually ventilated cages (IVC) with a controlled temperature (maintained at 22 ± 2 °C), relative humidity (kept at 40 - 60%), and a 12-h light/dark cycle. All of the experimental protocols have been approved by the Ethics Committee of Nankai University, approval number: 2022-SYDWLL-000589. Once the tumors were palpable, the mice were randomly assigned to different experimental groups. Randomization was carried out using a computer-generated randomization schedule to ensure unbiased allocation of animals to each group. Each group consisted of 6 mice.

Cell culture

PLC-PRF-5, A549, MCF-7, HCT-116 and HUVEC cell lines were bought from the KeyGen Biotech (Nanjing, China). B16-F10-luciferase, B16-F10-GFP, H22- luciferase, MC38 and B16F10-OVA cell lines were bought from Shanghai Zhong Qiao Xin Zhou Biotechnology, cultured in DMEM or 1640 medium supplemented with 10% fetal bovine serum (Biological Industries) and 1% penicillin-streptomycin solution (KeyGen) in a humidified environment containing 5% CO_2 at 37 °C. All cell lines were subjected to STR analysis, and the cell line mycoplasma-free status was verified using the MycoAlert mycoplasma detection kit (Lonza, LT07-218).

Preparation of SLCs and SLCV (MASKv) for immunotherapy

For the preparation of SLCs, 1×10^7 B16F10-luciferase cells were collected by centrifugation for 5 min at 800 rpm, and the cells were resuspended in 1 mL of PBS solution containing 100 mM $FeCl_3$, treated for 5 min, and then

centrifuged to collect the cells and washed three times with sterile PBS solution. Finally, SLCs were collected by centrifugation and resuspended in PBS and stored at 4 °C for use. To prepare SLCV (MASKv), one dose requires mixing 1×10^6 SLCs with 20 μg of MPLA (Invitrogen, tlrl-mpla).

Cell imaging

PLC-PRF-5, A549, MCF-7, HCT-116 and HUVEC cells were treated with PBS, 4% paraformaldehyde or 100 mM $FeCl_3$, respectively. Bright field and phase contrast microscopy images were then taken using a Nikon confocal microscope. The picture in the red dotted box in the phase contrast microscope image is enlarged for subsequent analysis. The intensity changes in the red dashed area were analyzed by NIS-Viewer software 5.21.00. For Live cell imaging, 3×10^6 PLC-PRF-5 cells were inoculated into 24-well glass culture dishes (NEST). After culturing for 12 h, freshly prepared 100 mM $FeCl_3$ solution was added to the well plate, and live cell imaging was performed immediately under the phase contrast microscope, and the during time was 1 min, and the time interval was 10 s.

Scanning electron microscopy

For scanning electron microscopy, PLC-PRF-5 cells were seeded in 24-well plates containing slides, and after treatment with PBS with or without $FeCl_3$, samples were fixed with 2.5% glutaraldehyde overnight at 4 °C. After washing three times with PBS, the samples were dried and dehydrated with graded ethanol and graded tert-butanol. The samples were concentrated at 4 °C and vacuum-dried overnight. The samples were sprayed with gold and then observed with a scanning electron microscope (SEM, COXEM).

Immunofluorescence staining

Cells were cultured on coverslips in 24-well plates, and then were washed three times with PBS, fixed with 4% paraformaldehyde for 20 min and permeabilized with blocking buffer (QuickBlock Blocking Buffer, Beyotime) for 30 min at room temperature. Subsequently, the cells were incubated with primary antibodies VEGFR-2 (Abcam, ab10972), beta Tublin (Affinity, T0023), GAPDH (Affinity, AF7021) for 2 h at room temperature. The cells were washed with PBS (3 × 5 min) and incubated with fluorochrome labeled secondary antibody for 2 h at room temperature. Finally, coverslips were stained with DAPI and the analysis of immunofluorescence using ZEISS LSM 800 Inverted Confocal microscope attached with an Airyscan area detector.

Proteomic analysis

The proteomic technology provided by Novogene Bioinformatics Technology Co., Ltd. (Beijing, China) was employed to comprehensively characterize the protein expression profiles of B16F10 cells before and after treatment with 100 mM $FeCl_3$. Briefly, total proteins were extracted from the samples, quantified, and then subjected to enzymatic digestion and desalting. The resulting peptides were analyzed by liquid chromatography-tandem mass

130   spectrometry (LC-MS/MS) in data-independent acquisition (DIA) mode. Raw mass spectrometry data were

131   processed and searched using DIA-NN software (Direct DIA) against the UniProt database

132   (Mus_musculus_uniprot_2024_07_26_Swissprot.fasta, 17,224 sequences), with a false discovery rate (FDR) set to

133   1%. Differentially expressed proteins were identified based on a fold change threshold of > 2.0 or < 0.5 and a *P*-

134   value < 0.05, as determined by Student's t-test.

135   **Cell viability and apoptosis assay**

136   The cell viability of SLCs was evaluated by Calcein/PI Cell Viability Assay Kit (Beyotime, C2015M), the staining

137   protocol followed the manufacturer's instructions. Green fluorescent calcein-AM and red fluorescent propidium

138   iodide (PI) were used to indicate live and dead cells, respectively, and stained cells were imaged using a confocal

139   microscope with a 488 nm laser and a 550 nm laser.

140   For apoptosis analysis, SLCs were stained using the Annexin V-FITC Apoptosis Detection Kit (Beyotime, C1062L)

141   and analyzed by flow cytometry (BD LSRFortessa) after incubation for 30 min at 4 °C.

142   **Cell proliferation assay**

143   Cell proliferation ability was assessed by Cell Counting Kit-8 (APExBIO, K1018). According to the manufacturer's

144   instructions, at 0, 24, 48 and 72 h after PLC-PRF-5 cells treated with $FeCl_3$, 10 μL of CCK8 solution was added to

145   each well, and incubated at 37°C for 2 h. The absorbance of each well was measured at a wavelength of 450 nm

146   using a microplate reader (Thermo Fisher).

147   **Wound healing assay**

148   For wound healing experiments, PLC-PRF-5 cells were seeded in 24-well plates and cultured. After the cells

149   developed a 90% confluent monolayer, use a sterile pipette tip to remove the cells evenly, and continue to culture

150   the cells in serum-free medium after treatment with or without $FeCl_3$ solution. At 0, 12, 24, and 48 h, the scratch

151   field of view was selected under the microscope, and the cell migration was photographed and measured. Wound

152   healing rate was analyzed by Image J software.

153   **Gelatin degradation assay**

154   To assess the invasive ability of SLCs, we performed a fluorescent gelatin substrate degradation assay. Porcine skin

155   gelatin (Thermo Fisher, G13187) diluted with 2% sucrose was used at a final concentration of 0.2 mg/mL. The PLC-

156   PRF-5 cells were inoculated on gelatin-covered 24-well slides, and after culturing for 6 h, 100 mM $FeCl_3$ was added

157   to treat the cells. After continuing to culture for 24 h, the control cells and SLCs were fixed with 4%

158   paraformaldehyde, and the cytoskeleton was labeled with YF 633-Phalloidin (US Everbright, YP0053S) and

159   mounted with DAPI. Finally, images were acquired using a Zeiss LSM 800 inverted confocal microscope. Gelatin

160 degradation was analyzed using Image J software.

161 **In vivo cell proliferation of SLCs**

162 To verify whether SLCs still have the ability to proliferate in mice, 3×10^6 SLCs or live B16F10-luciferase cells

163 were inoculated subcutaneously into mice, and the bioluminescence signal was monitored on day 18.

164 **Atomic force microscopy**

165 The DMT modulus of the sample was measured using a Bruker Dimension Icon atomic force microscope operated

166 in PeakForce Tapping mode. Prior to imaging, the SCANASYST-AIR probe (length: 115 μm, width: 25 μm, resonant

167 frequency: 70 kHz, spring constant: 0.4 N/m, Bruker) was calibrated using the thermal tune method to determine the

168 precise deflection sensitivity and spring constant. Scanning was performed in air at room temperature, with a scan

169 rate of 0.7 Hz and a peak force setpoint of 8 nN. In the Channels section, the parameters Height, DMT Modulus, and

170 Adhesion were selected for simultaneous mapping.

171 **Bioluminescent imaging**

172 The IVIS imaging system (Perkin Elmer) was used for bioluminescence imaging studies in mice. D-Luciferin

173 potassium (150 μg/g, meilunstar, 115144-35-9) was injected intraperitoneally into the mice, and the mice were

174 anesthetized when the peak fluorescein uptake was reached 10 min after the injection, and then imaged, and the

175 bioluminescent intensity was calculated using Living Image software.

176 **Isolation and activation of BMDCs**

177 To collect BMDCs, 7-week-old C57BL/6 mice were euthanized, sterilized by immersion in 75% ethanol, and the

178 tibiae and femurs were removed and the bones were rinsed with PBS to obtain bone marrow cells. After

179 centrifugation and collection, the bone marrow cells were cultured in RPMI-1640 medium (10% FBS) containing

180 20 ng/mL granulocyte/macrophage colony-stimulating factor (GM-CSF, Abclonal, RP01206) and 10 ng/mL IL4

181 (Abclonal, RP01161). On day 3, the supernatant is gently removed and the same fresh medium was added. On day

182 7, BMDCs were collected and spread evenly in 6-well plates at a density of 1×10^6 cells, with the experimental

183 group adding 1×10^6 SLCs-treated BMDCs and the wells without SLCs serving as the control group. After 48 h of

184 treatment, BMDCs were collected and cells were stained with antibodies CD40 (PTMa, PTM-5537), CD80 (PTMa,

185 PTM-5247), CD86 (PTMa, PTM-5570) and MHC II (Invitrogen, 14-5321-82), respectively. The secondary antibody

186 CoraLite 488-conjugated Goat Anti-Mouse IgG(H+L) (Proteintech, SA00013-1) or Rhodamine (TRITC)-

187 conjugated-Goat Anti-Rat IgG(H+L) (Proteintech, SA00007-7) was used, and analyzed using flow cytometry.

188 **In vitro tumor killing assay**

189 CD8$^+$ T cells were isolated and purified from the spleen of 7-week-old C57BL/6 mice using the CD8 T Cell Isolation

190   Kit (Biolegend, 480008). 1×10^6 B16F10-GFP cells were inoculated in six-well plates. CD8+ T cells were added to

191   bone marrow-derived dendritic cells (BMDCs) and co-cultured with B16F10-GFP cells (CD8+ T cells: BMDCs:

192   B16F10-GFP cells = 2: 1: 2). Additionally, BMDCs and CD8+ T cells were separately co-cultured with B16F10-GFP

193   cells at ratios of (BMDCs: B16F10-GFP cells = 1: 2) and (CD8+ T cells: B16F10-GFP cells = 1 : 1), respectively.

194   Experimental groups were established by adding specific numbers of SLC cells (1×10^5 or 5×10^5), along with

195   control groups without SLC cells. All co-culture systems were incubated for 48 h. Finally, the viability of B16F10-

196   GFP cells was analyzed by flow cytometry.

Detection of Tumor Antigen-Specific T Cells

198   B16F10 cells (3×10^6) were subcutaneously injected into the right flank of mice. The mice were then randomly

199   divided into four groups. On days 7, 10, and 13 post-tumor inoculation, the four groups were intravenously (i.v.)

200   administered phosphate-buffered saline (PBS), 1×10^6 SLCs, adjuvant (monophosphoryl lipid A, MPLA, 20

201   μg/mouse, Invitrogen, Cat# tlrl-mpla), or SLCV (a combination of MPLA and SLCs), respectively (n = 6). On day

202   16 post-tumor inoculation, splenocytes were collected, and tumor antigen-specific T cells were quantified using the

203   B16F10 tumor antigen-specific T cell detection kit (ESMDT-MB16-1). The following antibodies were used for

204   analysis: anti-mouse CD3 FITC (BioLegend, 100204), anti-mouse CD8a 605 (BioLegend, 100743), and anti-mouse

205   IFN-γ PE (Proteintech, PE-65153).

Subcutaneous tumor models and treatment

207   3×10^6 B16F10-Luciferase cells were injected subcutaneously into the right side of female C57BL/6 mice to construct

208   a melanoma tumor model, and the tumor dimensions of the mice were measured every two days using vernier calipers.

209   Tumor volume (mm^3) was calculated as length (mm) × width (mm) ^{2} × 0.5. And bioluminescence imaging was

210   performed on days 7, 12, and 18. For FeCl$_3$ treatment, when the subcutaneous tumor volume of mice reached 100

211   mm^3, 100 mM FeCl$_3$ was injected in situ at multiple points around the tumor every 3 days for a total of 3 injections

212   (n = 6). For SLCs treatment, 1×10^6 SLCs were intravenously injected (i.v.) on days 7, 10, and 13 after the mice

213   were subcutaneously inoculated with tumor cells, respectively (n = 6). For SLC vaccine treatment, mice were

214   intravenously injected (i.v.) with PBS, 1×10^6 SLCs, Adjuvant (MPLA, 20 μg/mouse, Invitrogen, tlrl-mpla), or SLCV

215   (combined treatment with MPLA and SLCs) on days 7, 10, and 13 after tumor inoculation, respectively (n = 6).

216   Unless otherwise specified, the control group was treated with PBS.

Immune memory effect of SLC vaccine

218   To investigate the immune memory effect of SLC vaccine, mice treated with SLC vaccine were re-challenged. Briefly,

219   3×10^6 B16F10-Luciferase cells were inoculated subcutaneously on the right side of the mice. When the tumor

220   volume reaches 80-100 mm^3, and the mice were intravenously injected (i.v.) with Adjuvant (20 μg/mouse) or SLC

221   vaccine on days 7, 10, and 13 after tumor inoculation, respectively (n = 6), and the tumors were completely excised

222   at day 16. Thirty days after the first tumor excision, 3×10^6 B16F10-Luciferase cells were inoculated subcutaneously

223   on the left side of the mice, and the tumor volume was recorded. When the tumor volume reached about 1800 mm^3,

224   the mice were euthanized and the tumors were isolated for flow cytometry analysis.

225   **Tumor-initiating assay**

226   Tumor-initiating abilities were investigated by limiting dilution and serial transplantation assays. 4 to 6-week-old

227   male and female C57BL/6 mice were first treated with adjuvant (MPLA), SLC or SLCV. Then they were injected

228   subcutaneously with 1000, 10^4 or 10^5 B16F10 cells. Tumor incidence and tumor latency were recorded. Tumor-

229   initiating frequency and P value were calculated using the Extreme Limiting Dilution Analysis (ELDA) software.

230   **Cytokine measurement by ELISA**

231   After 18 days of SLCs treatment, the immune response in C57BL/6 mice was examined. Briefly, 300 μL of blood

232   was collected by removing the eyeballs of mice, and after the blood was allowed to stand at room temperature for

233   30 min, it was centrifuged at 3000 rpm for 15 min to obtain the supernatant serum. Serum levels of IL-4 (proteintech,

234   KE10010) and TNF-α (proteintech, KE10002) were determined using ELISA kits.

235   **Magnetic measurement of SLCs**

236   The magnetic properties of the magnetic SLCs were measured using the equipment of the Physical Property

237   Measurement System (PPMS-9) within a magnetic field strength range of $\pm 4e^4$ (oe).

238   **Magnetic targeting therapy of MASK vaccine**

239   In order to investigate whether MASK vaccine with magnetic properties can exert a greater anti-tumor effect under

240   the action of a magnetic field, the therapeutic effect was evaluated using subcutaneous tumor-bearing mice. First, 3

241    $\times 10^6$ B16F10-Luciferase cells were injected subcutaneously into the right side of the mice for 7 days, and the mice

242   were randomly divided into four groups: PBS, Magnet, MASKv, and MASKv + Mag (n = 6). The mice were

243   intravenously injected (i.v.) with PBS or MASKv (MASKs 1×10^6 + Adjuvant 20 μg/mouse) on days 7, 10, and 13,

244   respectively. Mice in the Magnet or MASKv + Mag groups were maintained for 1 day after each PBS or MASKv

245   injection with a strong magnet bound to the tumor on the back of the mice. Tumor volumes were recorded every two

246   days during treatment. After 19 days of treatment, tumor tissues were collected for HE staining, IHC staining, and

247   flow cytometric analysis.

248   **Immunotherapy with MASK vaccine combined with α-PD-1**

249   As previously described, C57BL/6 mice subcutaneously inoculated with B16F10-Luciferase cells were randomly

250 divided into five groups: PBS, MASKv +M, α-PD-1, MASKv +α-PD-1 and MASKv +M+α-PD-1. On days 7, 10,

251 and 13 after tumor inoculation, mice were intravenously injected (i.v.) with PBS or MASKv, and for the α-PD-1

252 treatment group, 200 μg α-PD-1 monoclonal antibody (Bio X Cel, BE0273) was used to treat tumor-bearing mice

253 intraperitoneally (i.p.). Magnet processing group according to the previous method. Tumor volumes were monitored,

254 and the tumor tissues were collected to analyze the immune response.

255 **Immunohistochemical analysis**

256 Routine histological and immunohistochemical examinations were performed using tissue sections. Briefly, tumors

257 from each group of mice, or organs of heart, liver, spleen, lung, and kidney from some groups of mice, were harvested

258 after the experiment, fixed in 10% formalin, then paraffin-embedded, cut to 5 μm thickness, and fixed on slides.

259 H&E (Solarbio, G1121) staining and a series of IHC stains were performed according to the instructions. For IHC

260 staining, primary antibodies: Ki67 Rabbit PolyAb (proteintech, 27309-1-AP), Anti-CD8 alpha Mouse mAb (PTMa,

261 PTM-5186), plus Polyer HRP (Mouse/Rabbit) IHC Kit （MXB biotechnologies, Kit-9902）and DAB peroxidase

262 substrate kits (MXB biotechnologies, DAB-0031) were used. Finally, the slides were observed with a light

263 microscope.

264 **Flow cytometry analysis**

265 Tumor or spleen tissues from mice in each group were collected, the tumors were cut into small pieces with scissors,

266 and digested with 1 mg/mL collagenase IV (Solarbio, C8160) at 37 °C for 1 h. The digested tissues were filtered

267 through a 100 μm cell filter and collected to obtain a single cell suspension. Cells were fixed using 4%

268 paraformaldehyde for 20 min, followed by staining with a series of fluorophore-coupled antibodies for 30 min at

269 4 °C in the dark. The following antibodies were used: Anti-mouse CD45 APC (Invitrogen, 17-0451-83), anti-mouse

270 CD3 FITC (BioLegend, 100204), anti-mouse CD4 PE (Invitrogen, 12-0441-83), anti-mouse CD8 PE (sungene,

271 M10083-09D), anti-mouse CD8a 605 (BioLegend, 100743), anti-mouse CD62L APC (Invitrogen, 17-0621-82), anti-

272 Hu/Mo CD44 PE (Invitrogen, 12-0441-82), anti-mouse IFN-γ PE (Proteintech, PE-65153), anti-mouse TNF-α PE

273 (BioLegend, 506305). All samples were collected on a flow cytometer (BD LSRFortessa) and data were analyzed

274 by Flowjo software.

275 **Spatial transcriptomics sequencing**

276 As previously described, C57BL/6 mice 7 days after subcutaneous inoculation with B16F10-luciferase cells were

277 randomly divided into three groups: Control (PBS), MASKv D7 and MASKv D13, and each group applied an

278 external magnetic field after each dose according to the previous method. MASKv D7 were treated with MASKv on

279 days 1, 4; MASKv D13 were treated with MASKv on days 1, 4, 7, and 10, and all the tumor tissues were collected

280 three days after the last treatment. Finally, freshly tumor models were performed according to the Spatial

281 Transcriptomics protocol (10× Genomics Visium Cytassist). Briefly, after tumor tissues were fixed, HE stained, and

282 observed by imaging, the tissues were permeabilized according to the 10× Spatial kit (10× Genomics, Pleasanton,

283 CA). The mRNA of the permeabilized tissues were released and bound to the corresponding capture probe, followed

284 by library preparation and sequencing on the Illumina platform, and finally data visualization analysis was performed

285 based on the HE staining results.

286 **Analysis of spatial transcriptomics**

287 The Space Ranger software pipeline (version 1.0.0) provided by 10×Genomics was used to process Visium spatial

288 RNA-seq output and detect the brightfield microscopy images of tissue. We processed the unique molecular identifier

289 (UMI) count matrix using the R package Seurat (R 4.1.3). We first normalized the data with sctransform in order to

290 account for variance in sequencing depth across data points, detecting high-variance features, and stores the data in

291 the SCT assay. Top variable genes across single cells were identified using the method described in Macosko et al.

292 Briefly, the average expression and dispersion were calculated for each gene, genes were subsequently placed into x

293 bins based on expression. Principal component analysis (PCA) was performed to reduce the dimensionality on the

294 log transformed gene-barcode matrices of top variable genes. Cells were clustered based on a graph-based clustering

295 approach, and were visualized in 2-dimension using tSNE. Likelihood ratio test (LRT) that simultaneously test for

296 changes in mean expression and in the percentage of expressed cells was used to identify significantly differentially

297 expressed genes between clusters. Differentially expressed genes (DEGs) were identified using the FindMarkers

298 function of Seurat package. P value < 0.05 and |log2foldchange| > 0.5 was set as the threshold for significantly

299 differential expression. GO enrichment and KEGG pathway enrichment analysis of DEGs were respectively

300 performed using R based on the hypergeometric distribution.

301 **Quantification and statistical analysis**

302 Statistical analyses were performed using GraphPad Prism version 9 for Windows or R 4.1.3. Statistically significant

303 differences were calculated using two-tailed unpaired t-tests, or unpaired t test with Welch's correction, Pearson's

304 correlation, and Kaplan–Meier as needed. $P < 0.05$ was considered significant.

306 **Results**

307 **High concentrations of FeCl$_3$ can induce cell sculpture-like death *in vitro***

308   In an experiment to form Prussian blue nanozyme *in situ* in cells, FeCl$_3$ and K$_4$[Fe(CN)$_6$]-3H$_2$O

309   need to be added sequentially to the cells. When preparing various concentrations of $FeCl_3$ solutions,

310   an increase in the concentration resulted in an escalation of precipitates in complete medium,

311   DMEM+ Fetal Bovine Serum (FBS). This occurrence may be linked to the salting out of proteins

312   in FBS. It is noteworthy that there was almost no precipitate left in the solution once the $FeCl_3$

313   concentration reached 100 mM (Figure S1A, shown in red box). Continued increases in the

314   concentration of $FeCl_3$ also failed to yield a significant precipitate, albeit the solution's absorbance

315   increases steadily. This phenomenon was not observed in PBS or empty medium (DMEM), serving

316   as a control. In the complete medium, the absorbance of $FeCl_3$ exhibited a noticeable dip at the 100

317   mM concentration (indicated by the arrow in Figure S1B), indicating inhibition of protein salting-

318   out. We hypothesized the presence of an "antisalting effect" in this solution, which may have unique

319   implications. Accordingly, we added 100 mM $FeCl_3$ to the cells for observation. Upon the solution's

320   addition, a morphology distinct from that of viable cells and 4% PFA fixation promptly manifested

321   under the phase contrast microscope.

322   As shown in Figure 1A, using the typical epithelial-like cells PLC-PRF-5 as an example, bright

323   field and phase contrast microscopy images of live cells, cells fixed with PFA and cells treated with

324   100 mM $FeCl_3$ are shown. Under phase contrast microscopy, it can be observed that after treatment

325   with 100 mM $FeCl_3$, the boundaries between the cell membrane and the nuclear membrane become

326   clearer, the interior of the cell becomes translucent, and the cells, especially the nucleus, have a

327   more granular appearance. We repeated this experiment on lung cancer cells (A549), breast cancer

328   cells (MCF-7), colon cancer cells (HCT-116) and normal endothelial cells (HUVEC) and found that

329   these cells all showed similar characteristics after the addition of 100 mM $FeCl_3$ (Figure S1C). This

330   may be a new mode of death that does not rely on biological processes. Because the shape resembled

331   a sculpture, we named them "Sculpture-Like Cells" (SLCs). Statistics of the optical density of the

332   nucleus, nuclear membrane, cytoplasm, and cell membrane of living cells, PFA fixed, and 100 mM

333   $FeCl_3$-treated cells were observed under a phase contrast microscope. As shown in Figure 1B,

334   compared with live cells and cells fixed with 4% PFA, the optical density characteristics of cells

335   treated with 100 mM $FeCl_3$ are significantly different and the fluctuation range becomes larger. This

336   is the characteristic that can be identified by SLCs. To better observe the formation process of SLCs,

337   we took PLC-PRF-5 as an example and performed high-speed live cell imaging (Figure 1C and

338   Video S1), which can clearly show that after $FeCl_3$ addition for 20 s, the cells immediately showed

339 sculpture-like characteristics. To investigate whether the formation of SLC is specific to ferric

340 chloride, we treated the cells with various metal salts at the same concentration. After treating the

341 cells with ferric sulfate, we observed the same SLC formation as with $FeCl_3$ treatment. When treated

342 with equimolar concentrations of $FeCl_2$, $CuCl_2$, $AlCl_3$, and $ZnCl_2$, the cells exhibited some

343 morphological changes, but these changes were distinct from SLC (Figure S1D). This indicates that

344 the formation of SLC is primarily associated with trivalent iron ions and is independent of the type

345 of anion.

346   We further observed SLCs with a scanning electron microscope. As shown in Figure 1D, the

347 cell structure of SLCs is intact, but the surface is rougher. Compared with untreated live cells, there

348 are a large number of protrusions on the surface. By analyzing the forward angle (FSC) and lateral

349 angle (SSC) of cells by flow cytometry, it can be found that compared with normal fixed cells, the

350 FSC of SLCs has no obvious change, but the SSC increases significantly (Figure 1E), indicating

351 that the granularity of SLCs increased, which was consistent with the scanning electron microscopy

352 images. We performed transmission electron microscopy (TEM) analysis on both normal fixed cells

353 and SLCs. As evidenced in Figure S1E, compared to normal cells, $FeCl_3$-treated cells exhibited

354 preserved overall morphology, with intact cell membranes and clearly discernible nuclear envelopes.

355 Furthermore, chromatin condensation is evident, and the cytoplasm displays numerous vacuoles,

356 indicative of cellular stress. These findings align with the biochemical perturbations caused by $FeCl_3$

357 hydrolysis, which generates localized acidity and elevated ionic strength. We further investigated

358 whether SLCs also preserve proteins, DNA and other molecules. The proteins of living cells and

359 SLCs were extracted, subjected to SDS-PAGE, and then stained with coomassie brilliant blue.

360 Figure S1F shows that there is no significant difference in the protein bands obtained between the

361 two groups. By immunofluorescence and DAPI staining of cytoskeleton β-tubulin, cell metabolic

362 enzyme GAPDH and receptor VEGFR2 (Figure S1G), it can be seen that DNA and three proteins

363 can be detected in SLCs, and there was no significant difference from the normal cell group. These

364 results indicate that SLCs essentially retain DNA and proteins after $FeCl_3$ treatment.

365   We conducted proteomic analyses on normal cells and SLC. As illustrated in Figure S1H,

366 protein expression profiles between the two groups were highly correlated, with an R^2 of 0.93,

367 indicating nearly identical expression levels. The volcano plot in Figure S1I further shows that the

368 vast majority of proteins did not exhibit significant differential expression, with only 43 proteins

369 showing changes. These differentially expressed proteins were not enriched in programmed cell

370 death pathways but instead appeared to reflect basic cellular perturbations. Additionally, hierarchical

371 clustering of known programmed cell death markers (including apoptosis, pyroptosis, ferroptosis,

372 and necroptosis) in SLC and control viable cells (Figure S1J) revealed virtually no differences in

373 expression levels.

SLCs have no cell viability and tumorigenic ability

375   One week after the formation of SLCs, we noticed that they did not proliferate significantly, so

376 we further investigated whether the SLCs had died. Live/dead staining results showed that the cells

377 in the SLCs group all had dead cell signals and no live cell signals (Figure 1F). CCK8 kit was used

378 to detect mitochondrial activity, and the results showed that SLCs had almost no mitochondrial

379 activity (Figure 1G). AnnexinV/PI double staining flow cytometry analysis also showed that more

380 than 70% of SLCs were located in the Annexin V/PI double positive area, and more than 99% were

381 located in the Annexin V positive area (Figure S1K). The above results indicate that SLCs are

382 completely dead and have no cellular activity. Using the classic oncology wound healing assay and

383 fluorescent gelatin degradation experiment, we also saw that SLCs lacked the ability to migrate and

384 invade (Figure S1L-M). Additionally, we found that SLCs have a higher stiffness (evaluated by

385 Young's modulus) compared to PFA-fixed cells, which may be a unique feature of SLC (Figure 1H).

386   We further designed animal experiments, as shown in Figure 1I, to investigate whether SLCs

387 have tumor-forming ability *in vivo*. We used the C57BL/6 mouse subcutaneous transplantation

388 tumor model, and subcutaneously inoculated the mice with luciferase-labeled B16F10 cells (Control)

389 and B16F10 SLCs induced by $FeCl_3$ *in vitro*. The results showed that after inoculation of B16F10

390 cells in the control group, it grew rapidly under the skin of mice (Figure 1J-L). After 19 days, the

391 tumor volume reached the upper limit of animal ethics and the mice were euthanized (Figure S1N-

392 O). All mice inoculated with SLCs were still alive 150 days later (Figure 1M), and no tumor

393 formation was observed, indicating that SLCs do not have the ability to form tumors *in vivo*.

394   To further demonstrate that high concentrations of $FeCl_3$-induced cell death are not a form of

395 programmed cell death, we performed Western blotting to detect apoptotic markers (Cleaved

396 Caspase-3, PARP1), necroptosis markers (pMLKL), and ferroptosis markers (GPX4 and xCT) in

397 SLCs. As shown in Figure S1P-Q, the expression of these markers in SLCs was consistent with that

398   in live cells, indicating that FeCl$_3$-induced cell death is not any of these three major types of

399   programmed cell death. Considering these characteristics, we believe that the process is not a form

400   of programmed cell death.

401   **High concentrations of FeCl$_3$ induce the sculpture-like death of tumor cells in the body,**

402   **limiting tumor growth, but needs to be improved**

403   The results of cell experiments show that 100 mM FeCl$_3$ can cause cell death, loss of cell

404   viability and tumorigenic ability. Therefore, multiple injections of 100 mM FeCl$_3$ into the tumor

405   may be a way to limit tumor growth. We designed the experiment as shown in Figure S2A to

406   establish a luciferase-labeled B16F10 subcutaneous xenograft tumor model in C57BL/6 mice.

407   Tumor formation was observed on day 7. Thereafter, 100 mM FeCl$_3$ was injected into the tumor at

408   multiple sites every 3 days for a total of 3 injections, and tumor growth was monitored. When the

409   tumor reached the upper limit of animal ethics requirements, that is, on day 19 after tumor bearing,

410   the mice were sacrificed. *In vivo* animal imaging results (Figure S2B) showed that mice injected

411   with FeCl$_3$ at multiple points in the tumor had lower B16F10 luciferase signals and smaller signal

412   areas compared to the control group. We quantified the bioluminescence signals obtained by *in vivo*

413   imaging (Figure S2C) and calculated the measured tumor volumes (Figure S2D). It can be seen that

414   tumors injected with FeCl$_3$ at multiple points in the tumor have a significantly lower growth rate

415   than the control group. On day 19, the mouse tumors were isolated and weighed. It can be seen that

416   the weight of the tumors injected with FeCl$_3$ at multiple points in situ was also significantly lower

417   than that of the control group (Figure S2E). The above results show that the injection of 100 mM

418   FeCl$_3$ into the tumor can significantly inhibit tumor growth.

419   However, FeCl$_3$ is a strong electrolyte, and a concentration of 100 mM is relatively high. The

420   blood in animals is essentially a sol in liquid state. Consequently, when a large amount of FeCl$_3$

421   solution comes into contact with blood, rapid coagulation will occur, and the generated precipitates

422   are likely to cause blockages. Therefore, it is widely used as a hemostatic agent in clinical practice

423   and is also a classic reagent in the field of thrombosis research.[23]

424   Considering that FeCl$_3$ has certain harmful effects in the body, we next evaluated the safety of

425   intratumoral injection of high concentration FeCl$_3$. By observing the living conditions of the mice,

426   we found that the mice in the intratumoral injection group of FeCl$_3$ had dull hair color, were listless,

427 and ate less. We also made gross and pathological observations on various organs of the mice.

428 Although there was no significant difference in the weight of various organs of mice in the

429 intratumoral $FeCl_3$ injection group compared with tumor-bearing mice (Figure S2F), differences in

430 color were observed in the liver. The livers of mice in the control group were reddish, whereas the

431 livers of mice in the $FeCl_3$ injection group were pale yellow (Figure S2G). The combination of $FeCl_3$

432 and blood causes clotting [23]. We believe that the mice in the intratumoral $FeCl_3$ injection group

433 may have a light yellow color due to the obstruction of blood circulation and the failure of the liver

434 to receive sufficient blood infiltration.

435 In addition, hematoxylin and eosin (HE) staining results of various organs showed that the

436 degree of inflammatory cell infiltration increased in the liver and spleen of mice in the intratumoral

437 $FeCl_3$ injection group (Figure S2G-K). HE staining results in the tumor area showed that after

438 intratumoral injection of $FeCl_3$, large areas of necrosis and inflammatory infiltration occurred, and

439 there were SLCs with obvious characteristics such as brightened nuclei and increased cell

440 granularity near the necrotic area and inflammatory infiltration area (Figure S2L), which have

441 consistent characteristics with SLCs induced *in vitro*. The above results indicate that direct

442 intratumoral injection of high concentration $FeCl_3$ may have safety issues, but this treatment method

443 can significantly enhance the immune response. Therefore, we further investigated the possibility

444 of using SLCs obtained by pretreatment with high concentration $FeCl_3$ as immunotherapy.

445 **Intravenous injection of SLCs can activate the immune system *in vivo* and treat tumors**

446 As shown in Figure 2A, we pretreated B16F10 cells with high concentration of $FeCl_3$ *in vitro*

447 to obtain SLCs. Although the SLCs were repeatedly washed with PBS during preparation, we were

448 still concerned about the potential presence of high concentrations of iron ions. Therefore, we

449 measured the iron content in the SLCs. We found that the average iron content of SLC was 0.771

450 ng per 10^4 cells, while the average iron content of live cells was also 0.731 ng per 10^4 cells. The iron

451 content of SLC was only 1.05 times that of live cells, indicating that this concentration of iron is

452 within the normal range (Figure S3A). Additionally, we measured the iron content of the SLC eluate.

453 After placing 8×10^6 SLC in 2 mL of PBS for one day, the iron content of the supernatant was found

454 to be 0.08 μg/mL, which is below the national standard for iron content in drinking water (0.2 mg/L).

455 Therefore, we believe that SLC does not have iron-related toxic side effects. To investigate the

456   antitumor effect of SLCs *in vivo*, we subcutaneously inoculated luciferase-labeled B16F10 cells into

457   C57BL/6 mice and injected SLCs into the tail vein on days 3, 6, and 9 after tumor formation. The

458   control group was injected intravenously with equal volume of PBS. *In vivo* imaging (Figure 2B-C)

459   and tumor growth curve (Figure 2D) showed that the tumor growth of mice in the tail vein injection

460   group of SLCs was significantly inhibited and the survival time was also significantly prolonged

461   (Figure 2E). Various organ tissues were harvested from the mice (Figure S3B-F), and HE staining

462   was performed (Figure 2F). The results showed that mice in the SLCs injection group had no

463   obvious damage to various organs, indicating that SLCs in mice have no significant side effects in

464   the body. It is worth noting that the spleen, as the largest peripheral immune organ, plays an

465   important role in the immune response of the human body [24]. In the spleen tissues of mice in the

466   SLCs group, we observed that the size and number of splenocytes were significantly increased and

467   their structure was intact. HE staining of the tumor was then performed. The results are shown in

468   (Figure 2G), compared with the control group, the degree of tumor immune infiltration was

469   significantly increased in the SLCs group. The above results indicate that SLCs can effectively

470   stimulate immunity *in vivo*.

471   T cells play an important role in antitumor immunity and are the major cell type that kills tumor

472   cells and inhibits tumor progression. $CD8^+$ T cells are the end effectors of cancer immune responses

473   [25, 26], so we detected them by flow cytometry. As shown in Figure 2H-I, the proportion of

474   infiltrating $CD3^+$ T cells and $CD8^+$ T cells in the tumor tissue of the SLCs group was significantly

475   increased compared with the control group. Immunofluorescence staining of $CD8^+$ T cells was

476   performed on tissue sections from the tumor. As shown in Figure 2J, the proportion of $CD8^+$ T cells,

477   identified by CD8 staining, was significantly increased in the tumor tissue of the SLCs group

478   compared to the control group (Figure 2K), indicating that SLCs primarily promote the infiltration

479   of $CD8^+$ T cells into tumors. To further assess T cell activation, we measured the levels of three key

480   cytokines, IL-4 (Figure 2L), TNF-α (Figure 2M), and IFN-γ (Figure 2N). The results demonstrated

481   a significant increase in the levels of these cytokines in the SLCs group compared to the control

482   group, suggesting that SLCs can effectively activate T cells.

SLCs stimulate DC maturation and differentiation *in vitro* and promote T cell killing of B16F10 cells

Tumor cells and cell lysates can be used as tumor antigens, providing a variety of epitopes for vaccine preparation and inducing T cells in the body to produce immune responses. When the body mutates or foreign pathogens invade, DCs are one of the first immune cells to respond. As full-time APCs, mature DCs can initiate the body's innate immunity and promote the activation of antigen-specific T cells to kill tumors. The rough surface presented by SLCs may be more easily recognized by DCs, allowing T cells to more accurately identify and kill tumor cells. Therefore, we further investigated whether SLCs can promote DC maturation and differentiation. As shown in Figure 3A, we co-cultured SLCs with BMDCs isolated from mouse bone marrow *in vitro*, and then used flow cytometry to analyze the expression levels of DC maturation markers CD40, CD80, CD86, and MHC II. As shown in Figure 3B-C, compared with the control group, the expression of DC maturation markers was significantly increased in the SLCs and BMDCs co-culture group, indicating that SLCs promoted the maturation of BMDCs.

To further investigate whether SLCs can be presented to T cells by DCs so that T cells can kill B16F10 melanoma cells, we extracted BMDCs from mouse bone marrow and CD8$^+$ T cells from mouse spleen, and then designed a co-culture experiment with B16F10-GFP cells as shown in Figure 3D. After co-culture, the GFP signal is analyzed by flow cytometry, which can reflect the proportion of tumor cell survival. As shown in Figure 3E-F, the addition of SLCs, CD8$^+$ T cells, DCs, or any pairwise combination of these components did not have a significant killing effect on B16F10-GFP cells. When SLCs, BMDCs and CD8$^+$ T cells were added simultaneously, the B16F10 -GFP signal was significantly reduced in a dose-dependent manner with the amount of SLCs added. The above results indicate that SLCs must be presented to T cells by DCs in order to activate T cells and thereby produce significant killing effects on tumor cells.

SLCs and immune adjuvants are used to form SLC vaccines, which have stronger antitumor effects

Since we have seen that SLCs can stimulate the maturation and differentiation of DCs, thereby promoting T cells to kill tumors, we further explored the possibility of developing SLCs into therapeutic vaccines against tumors. Vaccines typically consist of antigens and adjuvants. SLCs

serve as antigens to stimulate immunity, and adjuvants can enhance the immunogenicity of antigens and induce stronger immune responses. Therefore, we combined SLCs with the immune adjuvant monophosphoryl lipid A (MPLA) to form the SLC vaccine (SLCV) and further evaluated the antitumor effect through animal experiments. As shown in Figure 4A, we subcutaneously inoculated B16F10 cells into C57BL/6 mice to evaluate the therapeutic effect of tail vein injection of SLCV on melanoma. The *in vivo* animal imaging results are shown in Figure 4B-C. The tumor volume of the SLCV group was smaller than that of the SLCs group, and the tumor growth rate was also slower (Figure 4D). The survival time of mice in the SLCV group was also significantly longer than that of other groups (Figure 4E). This indicates that SLCV is more effective than pure SLCs in inhibiting tumor growth and prolonging the survival of mice. Compared with the SLCs group, the proportion of infiltrating $CD3^+$ $CD8^+$ T cells in the tumor tissue treated with SLCV was further increased (Figure 4F-G).

To validate that the vaccine activated tumor-specific immune responses and that such responses were detectable in treated mice, splenocytes from mice subjected to different treatment regimens were analyzed using the B16F10 tumor antigen-specific T cell detection kit. Quantitative analysis revealed a significant increase in tumor antigen-specific T cells in the vaccine-treated group compared to controls (Figure S3G-H). The safety of SLCV is extremely important. Therefore, we performed both acute toxicity (24 h) and long-term toxicity (30 days) studies. For the acute toxicity study, we administered PBS, 1x, 2x, and 10x doses of SLCV to mice and monitored changes in body weight, body temperature, and behavior within 24 h. As shown in Figure S3I-J, none of the groups exhibited significant fluctuations in body weight or temperature, nor did they display abnormal behaviors such as convulsions, coma, lethargy, or increased aggression. We then extended the observation period to 30 days to assess long-term toxicity. The PBS, 1x, and 2x dose groups received SLCV every three days, while the 10x dose group did not receive additional doses after the initial administration. At the end of the experiment, we performed autopsies to examine various organs and conducted HE staining of the liver and kidneys. Throughout the experiment, the mice remained in good condition, with no abnormalities in pupils, respiration, or body temperature. There were no incidents of convulsions, coma, lethargy, increased aggression, or mortality. All mice showed weight gain, with no significant differences between the groups (Figure S3K-L). After 30 days, gross examination of the organs, particularly the liver and kidneys, revealed no significant abnormalities,

and HE staining showed no apparent pathological changes in the SLCV-treated groups (Figure S3M-P).

Long-term immune memory is one of the keys to evaluate the antitumor efficacy of vaccines. To investigate whether SLCV treatment can induce long-term immune memory *in vivo* after tumor resection, we established the tumor recurrence model shown in Figure 4H. The mice were rechallenged by inoculating B16F10 cancer cells for the second time on day 46,to evaluate the long-term immune memory effect of SLCV. The results showed that the growth of reinoculated tumors in the SLCV-treated group was significantly inhibited compared with the adjuvant group (Figure 4I). We isolated murine splenocytes on day 46 (corresponding to the second B16F10 tumor inoculation) and quantified the frequency of $CD8^+$ T cell subsets, including effector memory T cells, in each group using flow cytometry.. The results showed that injection of SLCV significantly increased the proportion of effector memory T cells ($CD3^+$ $CD8^+$ $CD44^+$ $CD62L^-$) (Figure 4J-L). The overall results indicate that tail vein injection of SLCV vaccine can induce effector immune memory, which is important for long-term prevention of tumor recurrence. We further investigated the tumor-initiating capacity in mice after injection with SLC and SLCV. As shown in Figure S4A, pre-immunization with SLC/SLCV followed by subcutaneous transplantation of B16F10 tumors leads to a reduction in both tumor formation rate and tumor-initiating cell frequency. This indicates that SLCV has the potential to prevent tumor formation.

Since there are many similarities between $FeCl_3$ and PFA-induced cell death, we further evaluated PFA-fixed cells using the subcutaneous B16F10 melanoma model. The results (Figure S4B-C) showed that MASK cells (SLC) had superior antitumor effects compared to PFA-fixed cells. We conducted an experiment comparing the antigen-presenting capability of live cells (Con), paraformaldehyde-fixed cells (PFA), and SLC to DCs (Figure S4D-E). The results show that after co-culturing the three types of cells with DCs, the proportion of MHC II-positive DCs was significantly higher in the SLC-treated group compared to the live and PFA-fixed cell groups. This indicates that SLC cells are more readily recognized by DCs, facilitating DC maturation and antigen presentation. Furthermore, we added $CD8^+$ T cells and GFP-labeled B16F10 cells to the co-culture system. By detecting the B16F10-GFP signal through flow cytometry, we evaluated the differences in T cell-mediated cytotoxicity against tumor cells after DCs were treated with the three types of cells. The results demonstrate that co-culturing SLC cells with DCs and T cells led to a stronger

572 cytotoxic effect on tumor cells compared to live cells and PFA-fixed cells.

573 Relevant studies have previously reported [13] that liquid nitrogen-treated tumor cells (LNT)

574 can be used as cancer vaccines and promote antitumor immune responses, thereby prolonging the

575 survival time of tumor-bearing mouse models. Therefore, we also compared SLCV with LNTV to

576 investigate whether the SLCV we prepared had more significant antitumor ability. C57BL/6 mice

577 subcutaneously inoculated with B16F10 cells were administered by tail vein injection, as shown in

578 Figure S4F-G, compared with the adjuvant alone group, both the LNTV group and the SLCV group

579 had better therapeutic efficacy, and the effect of tumor growth inhibition in the SLCV group was

580 significantly better than that of LNTV (Figure S4H). SLCV also showed better therapeutic effects

581 in terms of prolonging the survival of tumor-bearing mice (Figure S4I). We then determined the

582 proportion of tumor infiltrating T cells by flow cytometry. As shown in Figure S4J, the proportion

583 of infiltrating $CD3^+ CD8^+$ T cells in the tumor tissue of the SLCV group was significantly increased

584 compared with LNTV. The above results show that SLCV has a more significant therapeutic effect

585 than LNTV in tumor cell vaccines, there is no doubt that this has more positive significance for the

586 research of tumor therapeutic vaccines.

587 **Magnetic Sculpture-like (MASK) cells enhance vaccine efficacy through their enrichment in**

588 **tumors**

589 Since SLCs are induced by adding $FeCl_3$ solutions to cells and the SLCs suspension turns yellow

590 after centrifugation, it may interact with iron and be endowed with certain iron properties.

591 Magnetism is a property of iron and is relevant for targeted therapy, so we investigated whether

592 SLCs are magnetic. We placed the suspension of SLCs on a magnetic stand. After about 10 min, we

593 were very surprised to find that the SLCs were obviously enriched on one side of the magnet,

594 indicating that SLCs were magnetic (Figure 5A). We then performed a magnetic test on the SLCs,

595 and the hysteresis loop verified that the SLCs were magnetic (Figure 5B). Therefore, we also refer

596 to SLCs as Magnetic Sculpture-like (MASK) cells. Although the magnetic properties of MASK

597 cells of the same mass are weak compared to Fe_3O_4, they still have potential for targeted therapy.

598 We preliminarily investigated which biomolecule might contribute to the magnetic properties of

599 MASK cells. DNA, RNA, and protein were extracted from both B16F10 cells and B16F10 MASK

600 cells. After enrichment with a magnetic field of 0.2 T for 10 min, the concentrations were measured.

The results showed that the RNA extracted from MASK cells had a higher concentration after magnetic enrichment, which suggests that the magnetic properties of MASK cells might be attributed to RNA (Figure 5C, S5A). This finding was quite unexpected, and the underlying mechanism is difficult to study. It may require further investigation by researchers in the fields of biophysics and chemical biology. Nevertheless, this does not affect our evaluation of whether MASK cells can enhance therapeutic efficacy with the aid of a magnetic field.

Although cancer immunotherapy has made great progress, for solid tumors, since most antigens on the surface of solid tumor cells also exist in normal tissues, and there will be tumor cell heterogeneity within a solid tumor [27, 28]. Therefore, when the body's immune function is activated, normal tissues will also be attacked by T cells and cause irreversible damage. A major challenge for immunotherapy of solid tumors is how to activate immunity at targeted tumor sites. Therefore, we investigated whether the magnetism of MASK cells can cooperate with the magnets (Mag) placed at the cancer nest to activate the immunity of the tumor site more efficiently and further improve the effect of tumor immunotherapy. We designed an animal experiment as shown in Figure 5D. On the 7th day after inoculation of B16F10 in mice, melanoma signals could be detected by *in vivo* imaging (Figure 5E). Therefore, we placed magnets at the tumor site one day after inoculation with MASK cell vaccine (MASKv) and used *in vivo* imaging to track MASK cells. We can see that MASK cells are highly enriched at the tumor site (Figure 5E), indicating that MASK cells have sufficient magnetism to be distributed to a specific location under the influence of a magnetic field. After observing mouse survival and tumor volume, we found that the efficacy of MASKv was further enhanced under magnetic "navigation", the tumor volume was significantly reduced compared with MASKv (Figure 5F-G), and the survival period was significantly prolonged (Figure 5H).

HE staining of the tumor was performed, and the results are shown in Figure 5I. Compared with the control group, the necrotic area in the tumor area of the MASKv group increased, and the tumor necrotic area of the MASKv+Mag group was larger than that of SLCV. CD8 IHC can mark the degree of immune infiltration in the tumor area. The results showed that the immune infiltration of MASKv was significantly higher than that of the control group. The degree of immune infiltration in the MASKv+Mag group was further increased compared with SLCV (Figure 5I-J). The above results show that under magnetic navigation, MASKv can effectively locate the tumor area and

increase the degree of immune infiltration in the tumor area. At the same time, the IHC results of the tumor cell proliferation marker Ki67 (Figure 5K) showed that the Ki67 score of tumor cells in the MASKv+Mag group was significantly reduced, indicating that the tumor proliferation ability was weakened after treatment with SLCV+Mag. As shown in Figure 5L-M, compared with the control group, the proportion of infiltrating $CD3^+$ $CD8^+$ T cells in the tumor tissue of the MASKv+Mag group was significantly increased.

We used the H22-luc liver orthotopic transplant tumor model to observe the impact of a magnetic field on the distribution of MASK signals *in vivo* after injecting MASKv. As shown in Figure S5B, the red signal (MASKv) in the group without a magnet is relatively weak and dispersed throughout the mouse's body, with a slightly stronger signal in the abdominal area. However, after binding a magnet to the mouse's abdomen for one day, the red signal was localized in the liver region and overlapped with the liver cancer area (green). We collected blood samples at different time points within 0 to 24 h after tail vein injection of MASKv to detect the MASK signal. As shown in Figure S5C, the concentration-time curve indicates that, compared to the group without a magnet, the decline in peripheral blood MASK concentration in the magnet group was slower, with an extended half-life. This indicates that MASKv can be directionally enriched in the magnetic field area, increasing the concentration of MASK in that region and slowing its clearance.

In conclusion, our results demonstrate that magnetic MASKv can be enriched into solid tumor nests under the action of external magnetic fields, thereby activating immunity at a targeted location and improving the efficacy of immunotherapy.

Spatial transcriptomics reveals MASK vaccine has immunotherapy efficacy

To explore the pharmacological effects on tumors and TME structural heterogeneity under MASKv treatment, we performed spatial transcriptomics (ST) with B16F10 xenograft receiving MASKv and magnet treatment (Figure 6A). After quality control, based on unbiased clustering and spot features, spots were classified as 3 clusters of melanoma cells, E/M Status with high expression of Espn, Mpp2, Ndrg1 and Fosl2, erythrocytes with high expression of Hba-a2, Hbb-bs and Hbb-bt, epithelial cells with high expression of Wee1, Nr2f6 and Pnrc1, monocytes/T cells with high expression of Il1b, G0s2, Cxcl3, Cd14 and Ccl4, fascia cells with high expression of Col3a1 or keratinocyte with high expression of Krt5 and Krt14 (Figure 6B). We analyzed the proportion of

660   each cell subpopulation and found that the proportion of melanoma cells decreased after MASKv

661   treatment, especially when it dropped to 25% after 13 days of MASKv treatment, indicating that

662   MASKv has a better killing effect on melanoma (Figure 6C). Figure 6D shows the HE staining of

663   mouse melanoma tissues in the control group and after MASKv treatment for 7 days and 13 days.

664   Figure6E shows the results of cell type annotations corresponding to the spatial position. Figure6F

665   shows the cell grouping characteristics of the three samples.

666   The reported spatial expression of the melanoma signature gene *Sox10* (Figure 6G) shows that

667   Sox10$^+$ cells were significantly reduced after MASKv treatment, further supporting that MASKv

668   can have a therapeutic effect on tumors. The total spatial expression of DC markers (CD40, CD80,

669   CD86) [29] and the spatial expression of CD80 (Figure 6H) showed that after MASKv treatment,

670   CD80$^+$ cells increased significantly, and DC maturation marker expression increased, and DC

671   maturation marker-positive cells increased significantly, indicating that MASKv increased the

672   maturation of DCs in tumors and promoted their antigen presentation. The overall spatial expression

673   of T cell markers [30] and the spatial expression of CD8 (Figure 6I) showed that after MASKv

674   treatment, CD8$^+$ cells increased significantly, the expression of T cell markers increased, and the

675   number of positive cells increased significantly. This indicates that MASKv promotes the number

676   of CD8$^+$ T cells, enhances the function of T cells, and promotes the killing effect of T cells on tumors.

677   Further analysis of the spatial transcriptome data showed that the expression of marker genes *S100b*

678   and vimentin related to melanoma malignant progression and metastasis[31, 32] were

679   downregulated after MASKv treatment (Figure 6J), while inflammatory factor-related genes such

680   as *Ccl4* and *Tnf* [33] were upregulated after MASKv treatment (Figure 6K), indicating that MASKv

681   activated tumor immunity and inhibited the malignant evolution of tumors. We further analyzed the

682   impact of SLCV on various immune cells using mMCP-counter. As shown in Figure S6, in addition

683   to DC cells and T cells, the scores for memory B cells (associated with long-term immunity), NK

684   cells (associated with non-specific immunity), eosinophils, neutrophils, and mast cells (all related

685   to allergic reactions) increased after SLCV treatment. This suggests that SLCV may activate these

686   immune cells. Conversely, the score for regulatory T cells decreased after SLCV treatment,

687   indicating that SLCV may enhance tumor immunity by inhibiting regulatory T cells. Unexpectedly,

688   the scores for macrophages/monocytes decreased after SLCV treatment, implying that SLCV might

689   have an inhibitory effect on these cells. These findings demonstrate that SLCV has complex direct

690 or indirect effects on various immune cells. We performed live-cell imaging to observe whether

691 macrophages could swallow MASK cells. Video S2 shows that although RAW264.7 macrophages

692 exhibit behavior around MASK cells, the number of MASK cells does not significantly decrease

693 after 24 h, and the morphology of MASK cells remains relatively intact. This suggests that MASK

694 cells are not easily phagocytosed by macrophages.

Magnetically targeted MASK vaccine combined with PD-1 inhibitor has stronger antitumor effect

697 While we have demonstrated that the MASK tumor cell vaccine can effectively stimulate tumor

698 infiltrating T cells, T cell activity is reduced due to the influence of the immunosuppressive tumor

699 microenvironment. In various murine tumor models, tumor specific $CD8^+$T cells exhibit

700 characteristics of T cell exhaustion and dysfunction [34], thus weakening the therapeutic effect of

701 tumor cell vaccines. Clinically, checkpoint blockade therapy with PD-1 and PD-L1 antibodies has

702 been shown to significantly improve T cell depletion caused by the immunosuppressive tumor

703 microenvironment. Tumor cell vaccines can be combined with checkpoint blockade therapy to

704 enhance immunotherapy effect. Therefore, we combined MASKv with anti-PD-1 antibody to verify

705 its antitumor efficacy.

706 We found that a combination of intravenous MASKv administration and intraperitoneal anti-

707 PD-1 antibody achieved striking results. As shown in Figure 7A-C, MASKv combined with anti-

708 PD-1 almost prevented tumor growth and greatly prolonged the survival period of mice. On the 60th

709 day after tumor inoculation, half of the mice were still alive (Figure 7D). Tumor samples were

710 collected from tumor-bearing mice and analyzed by flow cytometry (Figure 7E-F). The results

711 showed that tumor infiltrating $CD8^+$ T cells were significantly increased in the combination

712 treatment group.

713 Cytotoxic T lymphocytes (CTL) can directly kill tumor cells by releasing perforin or

714 granzymes and are the key to immunotherapy. Therefore, we investigated the CTL induced in the

715 combination treatment group. IFN-γ is a typical marker of CTL cytotoxic activity. We measured the

716 content of IFN-γ^+ $CD8^+$ T cells in each group by flow cytometry and found that the number of IFN-

717 γ^+ $CD8^+$ T cells was significantly increased in the combination treatment group (Figure 7G-H),

718 indicating that the combined treatment group effectively promoted the generation of CTL. Similarly,

TNF-α^+ CD8$^+$ T cells (Figure 7I-J) were also significantly increased in the combination treatment group. At the same time, the IHC results showed that the staining intensity and the percentage of CD8$^+$ T cells were significantly higher in the combination treatment group (Figure 7K-L), consistent with the flow cytometry data.

The efficacy of cancer immunotherapy will vary widely in different tumor environments. In particular, tumor cell models overexpressing OVA have higher immunogenicity [35], so ICB immunotherapy may activate a more potent immune response. There are also related studies reporting that MC38 tumors are extremely sensitive to PD-1 [36]. Therefore, we evaluated the therapeutic efficacy of MASKv combined with anti-PD-1 antibody in B16 OVA and MC38 tumor models. We found that in the mouse subcutaneous tumor model, the combined treatment group had a very significant effect in the B16 OVA and MC38 tumor models, with tumor growth strongly inhibited and survival rate significantly improved (Figure S7A-C). At the same time, we obtained the same results in the mouse subcutaneous tumor recurrence model (Figure S7D-F). These results demonstrate that the treatment regimen of MASKv combined with anti-PD-1 antibody can have very excellent efficacy in various tumor models and has great prospects for clinical application.

Discussion

In this study, we discovered a new way of cell death—sculpture-like death. After cells are treated with high concentration of FeCl$_3$, the cells become magnetic and have a mask-like shape, so they are called Magnetic Sculpture-like (MASK) cells. Sculpture-like death differs morphologically from cell fixation induced by PFA, with cells exhibiting a rougher surface. All the cells we tested can undergo sculpture-like death, and this type of death can also be observed when high concentrations of FeCl$_3$ are directly injected into living tissues, indicating that the induction of MASK cells by high concentrations of FeCl$_3$ is efficient and universal. Sculpture-like death is not a programmed cell death (such as apoptosis, autophagy, ferroptosis, etc.) because the process of cell sculpture-like death takes less than one min. Such a short time is more consistent with the characteristics of chemical changes.

A large number of studies have shown that tumor cells can be used as therapeutic vaccines for tumors [16, 37, 38]. Compared with other whole tumor cell vaccines, MASK cells are unique in that they are treated with FeCl$_3$, so MASK cells should contain a certain amount of iron. In addition to

providing magnetism, iron is an important component of the blood. Studies have shown that iron can promote the formation of neutrophils and the production of inflammatory factors [39, 40], so MASK cells show a strong activating effect on the immune system. In addition, considering that iron overload is a condition in which excess iron is deposited in various organs [41], which may lead to the formation of MASK cells, the presence of MASK cells in related diseases remains to be investigated.

The future clinical application of MASK cells is the preparation of personalized autologous anonymous antigen vaccines. Specifically, the patient's tumor tissue is obtained by surgery or biopsy and treated *in vitro* with high concentrations of $FeCl_3$ to obtain MASK cells, which are combined with immune adjuvants to form a MASK cell vaccine, which is then reinfused into the patient's body by intravenous injection. Because the MASK cell antigen is derived from the patient's own tumor, it is more specific. The unique magnetic properties of MASK cells also allow them to be enriched in the tumor area through magnetic field navigation. The safety and efficacy of this therapy were evaluated in this study in a mouse model. The combination of MASKv and PD-1 antibodies under magnetic navigation can further enhance the antitumor effect and significantly prolong survival.

MASKv has four advantages. 1.Easy to prepare: Just add $FeCl_3$ solution to the cells at room temperature, and it can be obtained in less than 1 min without repeated operations; 2. Cost-effective, the price of $FeCl_3$ and simple operation save a lot of cost; 3. Effective: The rough shape of MASK cells and the iron they contain can further enhance the immune response. In addition, MASK cells retain their complete shape and are structurally more rigid under the action of iron, without being brittle caused by repeated freezing and thawing, and adhesion problems. Our data show that MASKv has a better effect on B16F10 subcutaneously transplanted tumors than previously reported liquid nitrogen treated B16F10 cells; 4. Navigable: MASKv can cooperate with magnetic fields to achieve directional enrichment and treatment of solid tumors.

In accordance with conventional wisdom, elevated concentrations of $FeCl_3$ typically induce protein salting out. Thus, we initially hypothesized that the magnetism observed in MASK cells stemmed from proteins. However, our findings were remarkably unexpected: the magnetism exhibited by MASK cells did not emanate from proteins or DNA, but rather from RNA. The chemical structure of the pentoses in DNA and RNA is very similar, but the DNA of MASK cells has almost no magnetic effect, whereas RNA has a magnetic effect. This selectivity surprised us.

778 This discovery may have important implications for future RNA research and magnetic biology

779 research. RNA is widely distributed in the nucleus and cytoplasm of cells. In recent years, it has also

780 been found to be distributed on the cell surface [42, 43], so that high-concentration $FeCl_3$ treatment

781 enables the whole cell to exhibit a strong and homogeneous magnetic effect, which is an important

782 basis for magnetic navigation, and may also lay the foundation for the future realisation of whole-

783 cell magnetisation and even magnetisation of tissues and organs.

784 Frankly, this study serendipitously discovered that high concentrations of $FeCl_3$ cause statue-

785 like cell death. However, the molecular mechanisms underlying this process remain elusive, as does

786 the cause of the observed magnetism, particularly regarding how RNA generates magnetism. Further

787 investigation is warranted to elucidate these phenomena. In addition, although this study shows that

788 high concentrations of $FeCl_3$ can induce sculpture-like death of various types of cells, the effect of

789 MASKv was studied using mouse B16F10 melanoma as an example, and the efficacy on other types

790 of malignant tumors requires further study.

901 **Figure 6. Spatial transcriptomics of the structural heterogeneity of Tumors and TME in**
902 **response to magnetic MASK vaccine treatment.**

903 **(A)** Graphical overview of spatial transcriptomics experimental design. **(B)** Uniform manifold

904 approximation and projection (UMAP) plots of integrated ST spots from the tumor tissues of

905 Control, MASKv D7 and MASKv D13. **(C)** Bar graph showing the proportion of each cell cluster

906 in each sample in the ST dataset. **(D)** H&E staining of three tumor tissue samples, and **(E)** unbiased

907 cluster analysis of ST spots. **(F)** UMAP plots of ST spots for three tumor tissue samples, respectively.

908 **(G)** The spatial feature maps illustrate the spatial expression of Sox10 in each tumor tissue. **(H-I)**

909 The spatial expression maps of dendritic cell markers (CD40, CD80, CD86) and CD80 in tumor

910 tissues **(H)**, and T cell markers (CD3E, CD3G, CD8A, IKZF2, THY1) as well as CD8A in tumor

911 tissues **(I)**. **(J)** The spatial expression maps of Vimentin and S100B in tumor tissues of different

912 treatment groups. **(K)** The spatial expression maps of CCL4 and TNF in tumor tissues of different
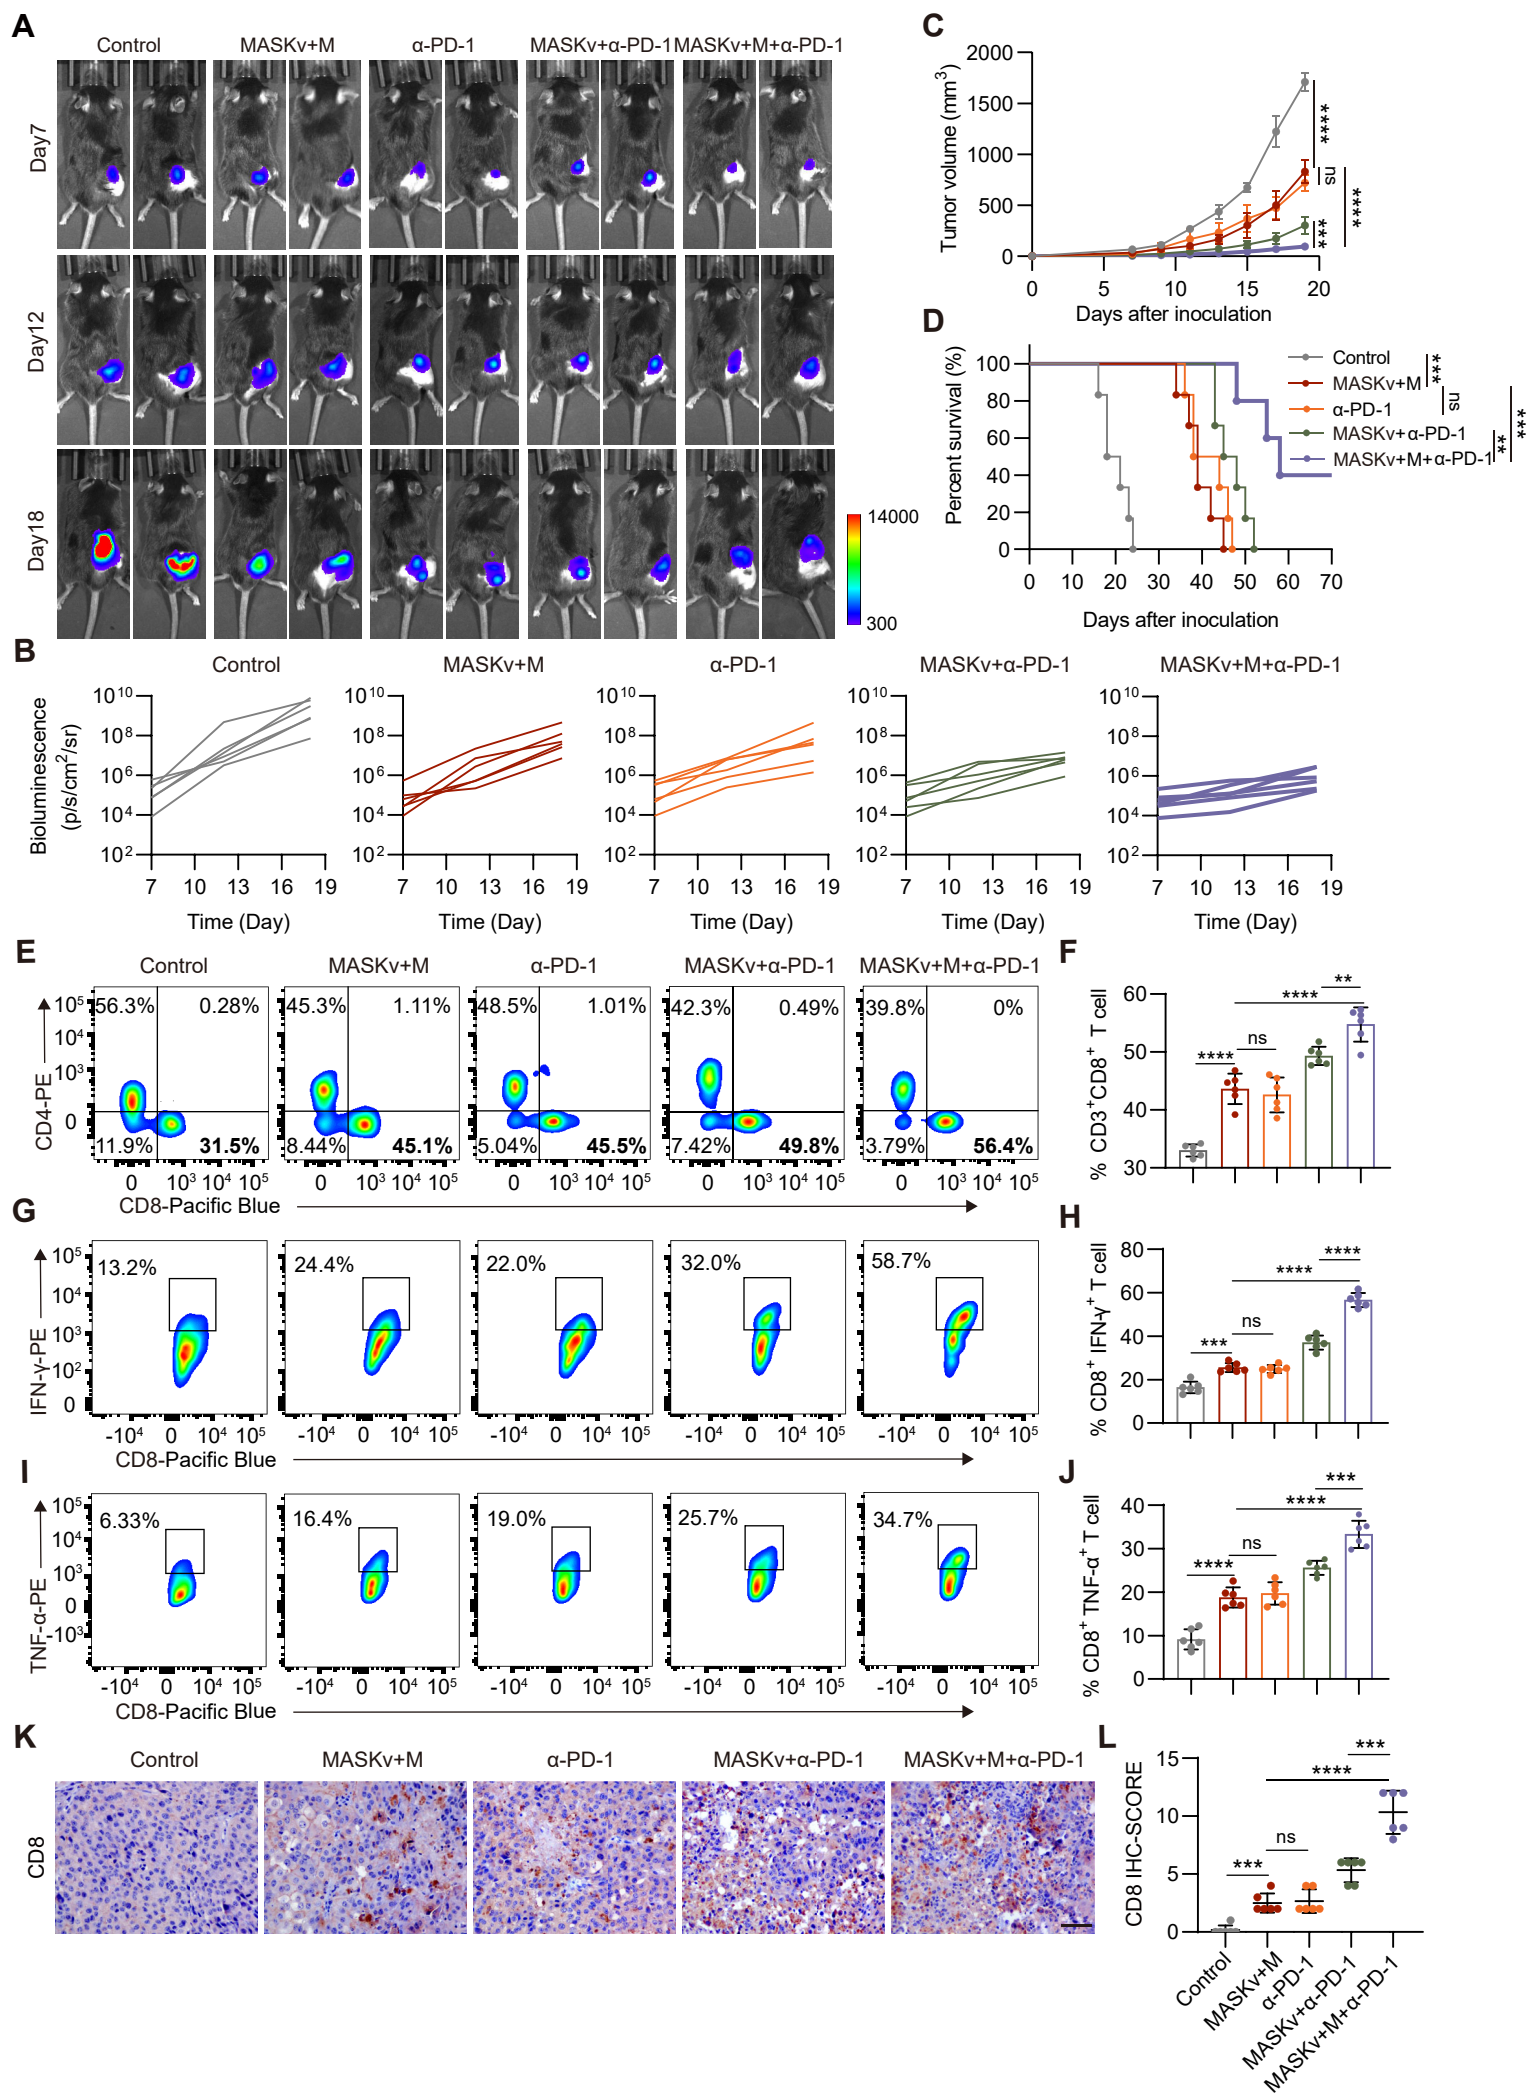

913 treatment groups.
